The charge-state distribution is defined as the charge-state probability distribution, i.e., the probability that the system has a certain number of ions in a certain charge state, e.g., cation and anion for Bi²⁺. The ionization probability is the ionization coefficients which has to be fitted with experimental data. The charge-state probability distribution is crucial to know as well as fitted-based ionization coefficients for several applications. To predict and optimize the charge-state distribution of a sample in the trap, the multinomial ionization coefficients should be obtained. The coefficients can then be used to calculate the charge-state distribution of the sample. However, the maximum number of charge states (n) for each ion will depend on the number of sample atoms in the trap. This has to be optimized in accordance with the minimum number of samples in the analysis. Here, the relative, absolute and overall deviation of measured and predicted charge-state distributions of He-Ar c6a93da74d
